A blanket restriction that hinders innovation is not the right way to solve a problem that affects a small portion of the US. Wifi on the 5GHz band may interfere with TDWR systems, but banning modification of firmware in all devices that use that band is just a bit too heavy handed for "solving" that problem. XDA-developers would shut down overnight, or go underground (more likely to go underground). The same goes for custom router firmwares that allow us to do things with our routers that the stock firmware wasn't capable of. If transmit power is an issue, lock the transmit power below a certain amount. if using certain bands is the problem, mandate that certain bands are off limits. completely banning modification of firmware to solve a minor issue that only affects a very small subset of the population is bad practice and would leave many more routers open to botnet attack and assimilation as manufacturers don't issue updates to routers more than a month or two old, to get you to "Upgrade to the latest hardware you -totally- need!" (read that "quote" with sarcastic voice)
