

I have discovered that after a disaster it was easier to get reliable information from outside the disaster area than from broadcast facilities within the affected area. I would propose that certain of the AM frequencies (similar to the old Conelrad system) be used for transmitting information to the affected area from outside the area. Temporary high powered transmitters can be used to beam a signal into the affected area. Since a common frequency would be used, it would be easy to find on a battery powered radio.
